

# Operators

There are different types of operators in C++. More detail can be studied [at this article](#).

## Various Operators

### 1. Arithmetic

```
void arithmetic() {  
    int x = 0;  
  
    x = x + 1;  
    x = x - 1;  
    x = x * 2;  
    x = x / 3;  
    x = x % 2;  
  
    x++;  
    x--;}  
}
```

### Bitwise Operators

```
void bitwise() {  
    int x = 0;  
  
    x = x | 0b0001;  
    x = x & 0b0000;  
    x = x ^ 0b0001;  
}  
void great_example_of_xor_operator() {  
}
```

```
int a = 1;
int b = 0;

// Check if a and b are exclusive from each other
if ((a == 1 && b == 0) || (a == 0 && b == 1)) {
    // ...
}

// We can actually do this:
if (a xor b)
// or
if (a ^ b)}
```

## 2. Assignment

```
void assignment() {
    int x = 0;

    x = x + 3; // full form
    x += 3;     // shortcut
    x -= 3;
    x *= 3;
    x /= 3;
    x %= 3;
    x &= 3;
    x |= 3;
    x ^= 3;
    x >= 3;}
```

## 3. Comparison

```
void comparison() {
    int x = 0;
    int y = 1;
```

```
if (x == y)
if (x != y)
if (x > y)
if (x < y)
if (x >= y)
if (x <= y)}
```

## 4. Logical

```
void logical() {
    int x = 0;
    int y = 1;

    if (x == 1 && y == 1)
    if (x == 1 || y == 1)
    if (! (x == 1 && y == 1) )}
```

# Operator Overloading

The operators would be boring if they were only applied to integers as demonstrated in the examples above. We can actually inform the C++ compiler what operators should do for our classes. Let's reuse the Vector of integers we built before and define some interesting operators.

```
// file: vector.hh
class Vector {
private:
    int* m_array;    // Pointer to dynamically allocated array
    int m_max_size; // Max size of the vector
    int m_size;      // Current size of the vector
public:
    Vector(int max_size);
    ~Vector();

    bool push_back(int value);
    int pop_back();
```

```
Vector operator+=(const Vector& other) const; // operator +=
Vector operator+(const Vector& other) const; // operator +
bool operator==(const Vector& other) const; // operator ==
bool operator!=(const Vector& other) const; // operator !=

Vector operator*=(int multiply_with); // * operator to multiply all integers by a number

// ...
};

// operator+ definition
Vector Vector::operator+=(const Vector& other) const {
    // allocate memory that can hold data from both vectors
    Vector result(this->m_max_size + other.m_max_size);

    for (int i = 0; i < m_size; ++i) {
        result.push_back(m_array[i]);
    }

    for (int i = 0; i < other.m_size; ++i) {
        result.push_back(other.m_array[i]);
    }

    return result;
}

Vector Vector::operator+(const Vector& other) const {
    Vector result(*this);
    result += other;
    return result;
}

// operator== definition
bool Vector::operator==(const Vector& other) const {
    const bool is_equal = true;
    if (m_size != other.m_size) {
        return !is_equal;
    }

    for (int i = 0; i < m_size; ++i) {
        if (m_array[i] != other.m_array[i]) {
```

```

        return !is_equal;
    }

    return is_equal;
}

// operator!= definition
bool Vector::operator!=(const Vector& other) const {
    return !(*this == other);
}

Vector operator*=(int multiply_with) {
    for (int i = 0; i < m_size; ++i) {
        m_array[i] *= multiply_with;
    }
    return *this;
}

```

Here is how the operators may be used:

```

void vector_plus_operator_example() {
    puts("Let's practice strings");
    Vector v1(6);
    v1.push_back(1);
    v1.push_back(2);
    v1.push_back(3);
    Vector v2(3);
    v1.push_back(4);
    v1.push_back(5);
    v1.push_back(6);
    // Use our operator to add contents of two vectors
    v1 = v1 + v2;
    v1.print();
}

void vector_multiply_operator_example() {
    Vector v1(6);
    v1.push_back(1);
    v1.push_back(2);
    v1.push_back(3);
}

```

```
// Multiply operator in action  
v1 *= 5;  
v1.print();}
```

# Exercises

## Vector library operators

Let's implement a few more operators for your vector library. Typically, the `[ ]` operator is implemented such that it returns a reference to one of the elements of the vector, but in our case, we will return a read-only value.

```
class Vector {  
private:  
    int* m_array;    // Pointer to dynamically allocated array  
    int m_max_size; // Max size of the vector  
    int m_size;      // Current size of the vector  
public:  
    Vector(int max_size);  
    ~Vector();  
  
    // First implement an "at()" API  
    // Return an element at a particular index  
    int at(int index);  
  
    // Secondly, implement the [] operator:  
    const int operator[](int index);}
```

## String library operators

Implement the following string operators, and also write unit-test code in `main.cpp` to test that the code you wrote actually functions correctly.

```
class string  
{  
    std::unique_ptr<char[]> m_string;  
    int m_max_length;
```

```
public:

    string(int max_length);

    string(const char *c_string);

    // -----
    // Implement the following operators
    // -----

    // Adds two strings together
    string operator+=(const string& other) const;
    // "hello world" - "world" = "hello"
    string operator-=(const string& other) const;
    // "hello" * 2 = "hellohello"
    string operator*=(int how_many_times) const;
    // Implement shift operators to trim beginning or end of string
    // 0b1101 >> 1 ==> 0b0110
    // "hello" >>= 1 ==> "hell"
    // "hello" >>= 3 ==> "he"
    string operator>>=(int shift_right_by) const;
    // similar to python for slice operation
    string operator<<=(int shift_right_by) const;
    // All comparison operators are applicable
    // string s1("hello"); string s2("world")
    // if (s1 == s2)
    // if (s1 != s2)
    bool operator!=(const string &compare_with) const {
        return !(*this == compare_with);
    }
    bool operator==(const string &compare_with) const {
        // todo
        return false;
    }

    // Implement comparison operators
    bool operator<=(const string &compare_with) const;
    bool operator>=(const string &compare_with) const;
```

```
bool operator<(const string &compare_with) const;
bool operator>(const string &compare_with) const;
bool operator!=(const char* compare_with) const;
bool operator==(const char* compare_with) const;
}
```
